Diaryliodonium Salt Photoinitiators for Cationic Polymerization

Department of Chemistry, Rensselaer Polytechnic Institute

James V. Crivello

Photoinitiated polymerizations are of increasing interest today because they address a number of energy, economic, environmental and social issues currently of major importance in the world. These polymerizations are employed in many industrial applications and can essentially eliminate air and water pollution since solvents are not required. Further, their consumption of energy is only a small fraction of that required for traditional thermally induced polymerizations. Work in this laboratory has focused on the development of novel classes of photoinitiators that make it possible to carry out cationic polymerizations at high speeds under UV irradiation. A key discovery [1,2] made in this laboratory was the observation that diaryliodonium salts are efficient cationic photoinitiators. These hypervalent iodine compounds are easily prepared and modified using a variety of straightforward synthetic methods. This makes it possible to tailor at will their physical properties such as melting points, solubilities, as well as their UV absorption characteristics. Diaryliodonium salts not only possess excellent photochemical quantum yields but paradoxically also have good thermal stabilities. This enables users to prepare shelf-stable solutions of diaryliodonium salt photoinitiators in a wide variety of highly reactive monomers. Currently, the diaryliodonium salt photoinitiators shown below are available from several commercial sources. These

compounds are finding many applications, for example, in photocurable coatings, printing inks, adhesives, among many others. They are widely employed as photoacid generators for use in the most sensitive photoresists used for integrated circuit fabrication and also in stereolithography for the construction of three-dimensional models.

Diaryliodonium salts are a series of stable, colorless, crystalline, ionic salts that are readily soluble in many organic solvents, but nearly insoluble in water. Especially useful is their excellent solubility in a wide variety of polar cationically polymerizable monomers. It was observed that all

diaryliodonium salts are photosensitive [3], however, only those bearing non-nucleophilic anions of the type MtX_n^- as indicated above are useful as photoinitiators of cationic polymerization. Considerable attention has been devoted to the elucidation of the mechanism of the photolysis of diaryliodonium salts [4,5]. The actual mechanism is quite complex and an abbreviated version is shown in equation 1 of Scheme 1.

$$Ar_{2}I^{+}MtX_{n}^{-} \xrightarrow{hv} \left[Ar_{2}I^{+}MtX_{n}^{-}\right]^{1}$$

$$Ar_{2}I^{+}MtX_{n}^{-} + Ar_{2}$$

$$Ar_{3}I^{+}MtX_{n}^{-} + Ar_{3}$$

$$Ar_{4}I^{+}MtX_{n}^{-} + Ar_{3}I^{+}MtX_{n}^{-}$$

$$Ar_{5}I^{+}MtX_{n}^{-} + Ar_{3}I^{+}MtX_{n}^{-}$$

$$HMtX_n + M \longrightarrow H-M^+ MtX_n^-$$
 (2)

$$H-M^+ MtX_n^- + nM \longrightarrow H-(M)_nM^+ MtX_n^-$$
 (3)

Scheme 1

The photolysis of a diraryliodonium salt produces the excited singlet that rapidly decomposes by both heterolytic and homolytic cleavage reactions to provide cations, radicals and cation-radicals. The quantum yield of this process is quite high and of the order of 0.7. The cations and cation-radicals interact with the surrounding environment, i.e. solvent, monomer or impurities, to generate the protonic acid, $HMtX_n$. If the anion, MtX_n^- , is selected such that a super acid (Hammett acidity -12 or lower) is formed, protonation of virtually any cationically polymerizable monomer, M, will take place (eq. 2) and

subsequent polymerization (eq. 3) will occur.

Phenyl-substituted diaryliodonium salts have their primary absorption bands in the wavelength region (220-250 nm). For this reason, they respond well to such emission sources such as medium pressure mercury arc lamps that emit in this region. However, for applications involving imaging, it is often necessary to employ longer wavelength emission sources such as lasers and light emitting diodes. Achieving spectral sensitivity at these wavelengths has been possible through the use of electron-transfer photosensitizers, PS. For example, polynuclear hydrocarbons such as anthracene, pyrene and perylene and their derivatives have been employed to provide sensitivity in the 300-530 nm region [6,7]. The mechanism of electron-transfer photosensitization is depicted in Scheme 2.

$$PS \xrightarrow{hv} [PS]^*$$
 (4)

$$\left[PS\right]^{*} + Ar_{2}I^{+} MtX_{n}^{-} \longrightarrow \left[PS \cdots Ar_{2}I^{+} MtX_{n}^{-}\right]^{*}$$
 (5)

$$\left[PS\cdots Ar_2I^+\ MtX_n^-\right]^* \longrightarrow \left[PS\right]^{t}\ MtX_n^- + Ar_2I\cdot \ (6)$$

$$Ar_2I \cdot \longrightarrow ArI + Ar \cdot$$
 (7)

$$[PS]^{\dagger} MtX_n^- + mM \longrightarrow Polymer$$
 (8)

Scheme 3

On the absorption of light, the photosensitizer, PS, gives the corresponding excited species [PS]* (eq. 4). An excited state complex (exciplex) is often formed as an intermediate between the onium salt and the excited photosensitizer (eq. 5). Next, the onium salt is reduced by a formal one electron-transfer between the two reaction partners (eq. 6). The rapid decomposition of the resulting unstable diaryliodine free radical (eq. 7) prevents back electron-transfer and renders the overall process irreversible. Lastly, (eq. 8), the photosensitizer cation-radical induces the cationic polymerization of the monomer.

Diaryliodonium salt photoinitiators can be used to conduct the polymerization of virtually every known type of cationically polymerizable monomer. Scheme 3 shows some typical examples of vinyl and heterocyclic monomers that have been photopolymerized.

Work in this laboratory has focused on three major classes of cationically polymerizable monomers included in Scheme 3: epoxides, oxetanes and vinyl ethers. These specific monomers are of interest since they undergo the most rapid rates of polymerization. A wide range of epoxide monomers is available commercially and many of these monomers are suitable for coatings, adhesives and printing inks. More recently, several new series of epoxide monomers have been prepared with high reactivities and excellent properties [8]. Oxetane monomers have many properties that are similar to epoxides [9]. Vinyl ethers display exceptionally high reactivity in photoinitiated cationic polymerization by diaryliodonium

salts and are most suited to high-speed printing ink applications.

Diaryliodonium salts have also found considerable use as photoacid generators in chemically amplified microelectronic photoresists [10]. Poly(4-*t*-butoxycarbonyloxystyrene) on exposure to UV light in the presence of a diaryliodonium salt gives poly(4-hydroxystyrene), carbon dioxide and isobutylene. The photoresist is then developed using aqueous base to give a positive image.

【会告】

第13回フォトポリマー講習会

協賛 日本化学会

会期 2003年8月19日(火)~20日(水)

会場 理窓会館 (東京理科大学) 新宿区神楽坂 プログラム

- I 基礎編 (8月19日)
- 1) 有機および高分子の光化学 理科大 山下 俊氏
- 2) フォトポリマーの材料設計とリソグラフィ

松下電器産業 遠藤政孝氏

- 3) 微細加工用レジスト材料と評価 シャープ 森 重恭 氏
- 4) 感光性ポリイミド

東工大 上田充氏

- Ⅱ 応用編 (8月20日)
- 5) ラジカルおよびカチオン硬化型樹脂とその応用 JSR 宇加地孝志 氏

- 6) 微細加工用レジスト 信越化学工業 河合義夫氏
- 7) 配線板用の材料動向

住友ベークライト 飯田隆久氏

8) コーティング用フォトポリマー(仮)

未定

9) 光化学と分子増幅

理科大 市村國宏氏

参加費 会員および協賛会員 30,000円 非会員 40,000円、学生 20,000円 いずれも要旨集(テキスト)代を含む

参加申込方法 FAX で事務局 (043-290-3462) まで 定員 95名 (定員になり次第締め切ります) 第 144 回フォトポリマー見学会・講演会 会期 9月 16日(火) 見学先 NHK 技術研究所 参加資格 当会会員のみ

【平成15年度総会報告】

日時 2003年4月17日(木) 13時00から 会場 理窓会館3F会議室 出席者数 会員16名、運営委員15名(委任状含む) 議案

- 1. 平成 14 年度事業報告承認の件
- 2. 平成 14 年度収支決算ならびに年度末貸借対照表承

参加申込方法 E-mail (miya@faculty.chiba-u.jp) にて事務 局まで。会員番号・参加者氏名・ご年令・所属・ご連絡 先を明記のこと。定員になり次第締切。申し込まれた方 に、後日、詳細な案内を送付いたします。

認の件

- 3. 平成 15 年度事業計画および収支予算承認の件
- 4. その他の事項

議事

会則に基づき、会長を議長として開会。懇話会会則第11 条により総会は成立。議案1、2、および3について承 認、議決された。

韓国最大の化学企業、LG Chemical Ltd.

A Photosensitive Materials Program's Activity in the Development of Photosensitive Coating Materials for the TFT-LCDs

Dr. Kim, Kyung-Jun

Photosensitive Materials Program,
Information & Electronic Materials Research and
Development(IEMRD)
LG Chemical Ltd. / Research Park / Daejon / Korea

Our Team, opened in June, 1996 belongs to the IEMRD (Information & Electronic Materials R & D) which is pursuing the development of high performance products in the fields of Displays / Circuit Board Materials / Reprographics / Optical Materials through the technology integration and fusion. At present, 20 researchers with respecting and understanding mind to share their creativity and challenging spirit are conducting research on the development of coating materials for LCD in our team.

Since we started the development of pigment-dispersed color filter resist for full color TFT-LCD in 1996, we have extended research items to all kinds of negative photo-sensitive coating materials such as:

 acryl-based color filter photoresists for notebook, monitor and TV (commercialized in 1999)

- highly transparent overcoat photoresist for protection and planarization of the color filter layer(commercialized in 2002)
- highly photosensitive column spacer photoresist for the patterned spacer to keep a constant and reliable cell gap uniformity of LCD panel(commercialized in 2002)
- 4) black photoresist for the resin black matrix with high electric resistivity and high optical density
- 5) thermally stable advanced overcoating materials for TOC(TFT-array on Color Filter) and thermally curable transparent overcoat materials as well as positive-mode photoresists including transparent insulating materials for a TFT-array and photoresists for microlithography.

We have been focusing on the acquirement of essential technologies concerned with photoresists and coating materials, and is now securing the world-class core technologies as follows;

- design and synthesis of matrix polymer(transparent thermoplastic, thermosetting and photo-curable polymer)
- 2) design and synthesis of photo-active compounds such as photo-radical initiators, photoacid generators (PAG) and photoreactive compounds, etc.
- organic pigment dispersion using special dispersants and functional additives
- 4) product solution formulation, characterization and

evaluation

- 5) control of various product properties
- 6) surface treatment and analysis
- 7) fine chemical analysis
- 8) ink-jet technology

and now, we constructed very reliable mass production plants in Daejeon and Chung-ju.

Since we have established excellent R & D group related with LCD materials and very reliable mass production system, we can help our customers by solving any technical problems concerned with development and production of TFT-LCDs. (http://www.rnd.lgchem.co.kr)
